Pressure-Enhanced Lattice Transformation in Nb₃Sn Single Crystal*

C. W. Chu

Department of Physics, Cleveland State University, Cleveland, Ohio 44115 (Received 5 August 1974)

We report the first observation of pressure-enhanced lattice transformation in the high-temperature superconductor Nb_3Sn . The opposite pressure effects on the lattice transformation and the superconducting transition in A15 compounds can thus be understood on the basis of the Weger-Labbé-Friedel model by taking into account the pressure-induced interband charge transfer.

Many high-temperature superconductors exhibit a lattice transformation from cubic to tetragonal symmetry at temperature T_L above their superconducting transition temperature T_c . This concurrence of lattice transformation and high-temperature superconductivity has stimulated extensive investigations, both experimental and theoretical, on the two phenomena.¹ Hydrostatic pressure studies were recently made on T_L and T_C of near equiatomic V-Ru,² (Hf_{1-x}Zr_x)V₂,³ and $V_3 Si^4$ compounds. Without exception, T_L always decreases while T_c increases with pressure. In view of the negative pressure dependence of T_c in polycrystalline Nb₃Sn,⁵ the determination of the pressure behavior of its T_L is particularly important in the understanding of lattice transformation and high-temperature superconductivity. We have determined calorimetrically the pressure dependence of T_L of an Nb₃Sn single crystal up to 18 kbar. For the first time, lattice transformation was observed to be enhanced by the application of hydrostatic pressure in a high- T_c superconductor. T_c was also measured inductively at different pressures. It is suppressed by pressure at the same rate as that previously observed for polycrystalline samples.⁵

An ac temperature-modulation technique⁶ was employed to determine the temperature variation of the relative specific heat C_p and the temperature derivative R' of the resistance of the Nb₃Sn single crystal under hydrostatic pressure. It is a combination of the high-pressure clamp technique and an ac calorimetric method. The pressure medium was a fluid mixture of 1:1 n-pentane and isoamyl alcohol. A superconducting lead manometer situated next to the sample was used to measure the pressure at low temperature. The pressure change⁷ due to cooling usually is small and was shown to occur mainly at the freezing of the pressure medium. The pressure medium used freezes at ~180 K at atmospheric pressure. Hence the quoted pressure is that

determined at low temperature (7 K). The temperature of the sample was determined by a Au plus 0.07% Fe-Chromel thermocouple and/or a Ge thermometer depending on the temperature range.

The Nb₃Sn sample studied was part of the RCA single crystal which was observed⁸ to transform . at low temperature in the x-ray-diffraction and neutron-scattering experiments. The resistance ratio between 300 and 20 K was 7. The lattice transformation was clearly evidenced by anomalies in C_{ν} , R', and resistance R. At atmospheric pressure, both in the absence and then in the presence of the pressure medium, T_L was found to be ~43 K which is ~2 degrees lower than that previously observed.8 This may be due to the inhomogeneous nature⁹ of the big crystal from which our small sample was cut. In Fig. 1, the temperature dependence of the relative C_{\bullet} is shown at several pressures. The numbers underlined represent the sequential order of the experimental runs and the others stand for the pressure in kilobars. The arrow bars define the width of the lattice transformation, which varies from a few tenths of a degree at low pressure to about one degree at 18.3 kbar. Over the same temperature region, R exhibits a drop which gives rise to a large peak in R' corresponding to a change of over 100% at atmospheric pressure, as depicted in the inset of Fig. 1. However, at high pressure, e.g., >10 kbar, the R drop becomes sluggish and the R' peak degenerates into a broad jump. T_L defined above was plotted as a function of pressure in Fig. 2. It is enhanced by the application of hydrostatic pressure, linearly with $dT_L/dP = +(2.8 \pm 0.1) \times 10^{-4}$ kbar⁻¹ for P > 5kbar but nonlinearly at a higher rate for P < 5kbar, in contrast to $dT_L/dP = -(1.5 \pm 0.1) \times 10^{-4}$ kbar⁻¹ for V₃Si for pressures up to 18 kbar.⁴ dT_L/dP is estimated to be + (3.3 ± 0.3)×10⁻⁴ kbar⁻¹ as P approaches zero. In the same figure, the pressure dependence of T_c determined

inductively was shown to be $-(1.40\pm0.05)\times10^{-5}$ kbar⁻¹. This is identical to that recently measured calorimetrically.¹⁰ Hence the T_C data so obtained are characteristic of the tetragonal phase of the sample. $|dT_C/dP|$ is 2–3 times smaller than that for V₃Si.⁴

It has been shown that many of the unusual physical properties at atmospheric pressure of high-

T_c A15 compounds, such as Nb₃Sn and V₃Si, could be understood in the framework of the Weger-Labbé-Friedel (WLF) model.¹¹ According to this model, the band structure exhibits sharp and narrow density-of-states peaks at the d sub-band edges, characteristic of the linear-chain arrangement of the transition-metal atoms in the A15 compounds. The relative position of the Fermi level with respect to the band edge depends on the number of d electrons in the sub-band Q. The Q dependence of both T_L and T_C for cubic Nb₃Sn and V₃Si were calculated by Labbé, Barišić, and Friedel.¹² They found that T_L and T_C , instead of being monotonically varying functions of Q, peak at Q_{LM} and Q_{CM} , respectively, as shown in Fig. 3. T_L drops back to zero when Q $> Q_0$. Because of the larger Q and less localized atomic d orbital for Nb₃Sn, its Q_{LM}/Q_{CM} ratio was found to be >1 in contrast to the case of <1for V₃Si. In addition, Labbé, Barišić, and Friedel¹² also estimated that $Q_{CM} \simeq Q < Q_{LM}$ for Nb₃Sn while $Q_{CM} > Q \simeq Q_{LM}$ for V_3 Si. The application of hydrostatic pressure will undoubtedly bring the linear chains closer together and will thus lead to a redistribution of charges in different bands. Therefore the observed opposite pressure effects on T_L and T_C of Nb₃Sn and V₃Si can easily be understood qualitatively in terms of the WLF model, provided that pressure enhances Q of these compounds and that Q remains in between Q_{LW} and Q_{CM} . Any crossover between Q and Q_{LM} or Q_{CM} will result in a sign change of dT_L/dP or dT_c/dP . In addition, the observed smaller value of $|dT_L/dP|$ for V₃Si can be attributed to the close proximity of Q to Q_{LM} , and that of $|dT_c|$ dP for Nb₃Sn to the close proximity of Q to Q_{CM} . It should be noted that the experimental T_c results of the transforming samples are for tetra-

gonal lattice¹⁰ while the calculated T_c -Q relation is for the cubic lattice. However in view of the small effects^{1,10,11} of the lattice transformation on the electronic properties of Nb₃Sn and V₃Si, we believe that the general T_c -Q behavior for the tetragonal lattice is similar.

Recently the temperature dependence of the pressure coefficient of the shear modulus of V_sSi was observed¹³ to decrease from a positive value to a negative minimum before reversing the sign back to positive at lower temperature. To explain this anomalous behavior and the negative dT_L/dP of V₃Si, it was proposed^{4,14} that the WLF model should be extended to include effects due to the pressure-induced interband charge transfer. By fitting the experimental data, Ting and Ganguly and Barsch and Rogowski found⁴ that pressure indeed enhances Q. Using Ting and Ganguly's estimate, we found that at 20 kbar Qincreases by ~10% but still lies below Q_{CM} , in agreement with the observation of positive $dT_c/$ dP at this pressure.¹⁵ According to this model, a pressure of ≥ 34 kbar is needed to raise Q to above Q_{CM} such that dT_c/dP changes to negative sign. Earlier it⁴ was determined through extrapolation that ~ 24 kbar is sufficient to stabilize the cubic lattice in V_3 Si, suggesting that $Q_0 < Q_{CM}$, consistent with the recent observation of positive dT_{c}/dP for both the transforming and nontransforming V₃Si samples.¹⁶ On the other hand, Labbé, Barišić, and Friedel¹² obtained $Q_0 > Q_{CM}$.

$$C_s(T_L) = 0 = \frac{1}{2}Na^2q^2 \int_{|E_0|}^{|E_0|} dE \, nE(f + E\partial f/\partial E) + C_s',$$

where to the constraint

$$Q = \int_{-|E_0|}^{|E_0|} dE \, nf,$$

where $n = (4/\pi)[2|E_0|(|E_0|+E)]^{-1/2}$ is the density of states of the *d* sub-band; $f = [1 + \exp(E - E_F)/kT_L]^{-1}$, the Fermi function at T_L with Fermi energy E_F ; 3N is the number of transition metal atoms per unit volume; *a* is the interatomic distance, *q* the Slater coefficient of the atomic *d* orbital, $|E_0|$ the halfwidth of the *d* sub-band, and C_s' the temperature-independent part of C_s . Under pressure, with strain $\epsilon = \kappa P/3$, $N \to N(1+3\epsilon)$, $|E_0| \to |E_0| \exp(aq\epsilon)$, $a \to a(1-\epsilon)$, $T_L \to T_L + (\partial T_L/\partial \epsilon)\epsilon$, and $Q \to Q + \delta Q$. By keeping only the first-order terms of ϵ in the Taylor's expansion of Eq. (1), we have

$$\frac{\partial \ln T_L}{\partial P} = + \frac{\frac{1}{6}N\kappa a^2 q^2 \int_{|E_0|}^{|E_0|} dE \, nE\left[(1+aq)f + (1+2aq)E\partial f/\partial E + (aqE - \partial E_F/\partial \epsilon)(\partial f/\partial E + E\partial^2 f/\partial E^2)\right] + \partial C_s'/\partial P}{\frac{1}{2}Na^2 q^2 \int_{|E_0|}^{|E_0|} dE \, nE\left[(E-E_F)(\partial f/\partial E + E\partial^2 f/\partial E^2) + E\partial f/\partial E\right]}.$$
(3)

The term $\partial E_{\rm F}/\partial\epsilon$ in Eq. (3) is determined by Eq. (2), allowing $Q \rightarrow Q + \delta Q$ under stress. It is interesting to note that the numerator can be identified with $(\partial C_s/\partial P)_{T_L}^{-14}$ and the denominator with $-T_L(\partial C_s/\partial T)_P$ provided $\partial E_{\rm F}/\partial T$ is negligibly small. Hence Eq. (3) is reduced to the familiar

This disagreement may be attributed to the uncertainties associated with the physical parameters used in their calculation. Lack of experimental data prevents us from making a similar comparison for Nb₃Sn. However a discussion of the experimental results at atmospheric pressure of doped Nb,Sn in terms of the WLF model is worthwhile. For Nb₃Sn_{1-x}Al_x,¹⁷ a slight replacement of Sn by Al results in a decrease of Q and hence a decrease of T_L but an increase of T_C , as was observed. With large x, e.g., ≥ 0.08 , the lattice remains cubic below T_c , while T_c still increases. This absence of lattice transformation may arise from the higher density of imperfections in the crystal lattice, as for the case of V₃Si.¹⁸ However for Nb₃Sn_{1-x}Sb_x,¹⁹ the substitution of Sb for Sn not only increases Q but also changes the ratio c/a from <1 to >1. The ratio \cdot Q_{LM}/Q_{CM} may consequently shift from >1 to <1. The observed x-independent T_L and x-decreasing T_c are thus not unlikely. Studies of T_L and T_c of these samples under hydrostatic pressure, where presumably only Q variation is important, are planned to check the explanation of the doped-Nb₃Sn results, suggested above.

Recently Ting and Ganguly¹⁴ calculated the isothermal pressure coefficient $(\partial C_s/\partial P)_T$ of the shear modulus C_s , on the basis of the WLF model. By extending their formalism and using their notation, we have obtained an expression for dT_L/dP . T_L is defined as the temperature¹² at which the shear modulus C_s vanishes, i.e.,

(2)

form $(\partial T_L/\partial P) = -(\partial C_s/\partial P)_{T_L}(\partial C_s/\partial T)_P^{-1}$ whose validity has been demonstrated for $V_3 Si.^{14}$ Lack of information about $\partial C_s/\partial P$ for Nb₃Sn makes the determination of δQ and consequently of $\partial E_F/\partial \epsilon$ very difficult. No attempt is made at using Eq. VOLUME 33, NUMBER 21

(3) for any numerical calculation of $\partial T_L/\partial P$ for Nb₃Sn. A similar calculation on dT_C/dP , including the interband charge-transfer effect, can be done.

In conclusion, we have observed for the first time pressure-enhanced lattice transformation in a high- T_c superconductor. The opposite pressure effects on T_L and T_c of Nb₃Sn and V₃Si can be explained in terms of the WLF model by taking into account the pressure-induced interband charge transfer. Previous atmospheric results on T_L and T_c of doped Nb₃Sn samples were discussed and an expression for dT_L/dP was also obtained.

The author would like to thank Dr. L. R. Testardi for stimulating discussions throughout this work and Dr. L. J. Vieland for the sample. Valuable discussions with Dr. C. S. Ting and Professor G. R. Barsch are gratefully acknowledged.
