

of 11 605.6°K),

$$p_1(V_s) = -2.467 + 6.769\eta - 6.956\eta^2 + 3.040\eta^3 - 0.3869\eta^4,$$

$$a(V_s) = -0.2267 + 0.2712\eta,$$

$$b(V_s) = 0.08316 - 0.07804\eta^{-1} + 0.03068\eta^{-2},$$

with $\eta = V_s^0(T^0)/V_s = \rho/\rho_0$ being the compression of the material relative to its normal crystal density of 2.25 g/cc. The numerical coefficients were obtained by fitting expression (2) to points on the shock Hugoniot of graphite¹⁵ and to the compressibility and thermal expansion coefficient at normal density. The range of applicability is $0.95 < \eta < 2.5$, $0 < T < 2$.

2. THEORY

If solid carbon is considered, expressions are needed for the thermodynamic functions of both gas and solid phases; these may be derived by standard thermodynamic methods, and are summarized here.

For the gaseous component with equation of state (1),

$$E = \sum x_i(E^0 - H_0^0)_i + \sum x_i(H_0^0)_i + RT[\alpha T(F-1)/(T+\theta)], \quad (3a)$$

$$S = \sum x_i(S^0)_i - R[\sum x_i \ln x_i + \ln(p/p^0)] + R[\ln F - (e^{\beta x} - 1)/\beta + \alpha T(F-1)/(T+\theta)], \quad (3b)$$

$$\mu_i = (F^0 - H_0^0)_i + (H_0^0)_i + RT \ln(x_i p/p^0) - RT[\ln F - (e^{\beta x} - 1)/\beta - \kappa k_i(F-1)/k], \quad (3c)$$

where the gas imperfection factor F is defined in Eq. (1) and should not be confused with the (Gibbs) free energies F^0 and F_s' .

For the solid with equation of state (2),

$$E = (H^0 - H_0^0) + H_0^0 - (pV_s)^0 + \int_{V_s^0}^{V_s} [b(V)T^2 - p_1(V)]dV, \quad (4a)$$

$$S = S^0 + \int_{V_s^0}^{V_s} [a(V) + 2b(V)T]dV, \quad (4b)$$

$$\mu = (F^0 - H_0^0) + H_0^0 + F_s', \quad (4c)$$

where

$$F_s' = pV_s - (pV_s)^0 - \int_{V_s^0}^{V_s} [p_1(V) + a(V)T + b(V)T^2]dV.$$

For chemical equilibrium,

$$\ln \Pi_g(\nu_i)^{\nu_i} = \ln K_p(T) - (\sum_g \nu_i) \ln(p/n_g p^0) + (\sum_g \nu_i) \left(\ln F - \frac{e^{\beta x} - 1}{\beta} \right) - \frac{\sum_g \nu_i k_i}{k} (F-1) - \frac{\nu_s F_s'}{RT}, \quad (5)$$

¹⁵ J. M. Walsh, private communication. The measurements were made by a dynamic method similar to that used for aluminum, copper, and zinc by J. M. Walsh and R. H. Christian [Phys. Rev. 97, 1544 (1955)].

where

$$RT \ln K_p(T) = - \sum \nu_i (F^0 - H_0^0)_i - \sum \nu_i (H_0^0)_i$$

(one such equation for each independent chemical reaction).

In Eqs. (3) to (5) E , S , and μ are internal energy, entropy, and chemical potential, respectively. A superscript 0 refers to the reference state (ideal gas or real solid at pressure p^0 and temperature T),¹⁶ with H_0^0 being the enthalpy of formation from the elements at absolute zero; x_i and n_i are the mole fraction and number of moles of component i ; and $n_g = \sum_g n_i$. In Eq. (5) the ν_i 's are the coefficients of the chemical reaction, positive for products and negative for reactants, and the subscript g for a sum indicates it is for gaseous components only.

The thermodynamic state of the detonation products is defined by the Hugoniot equation¹⁷

$$h \equiv E - E_0 - \frac{1}{2}(p + p_0)(V_0 - V) = 0, \quad (6)$$

and the Chapman-Jouguet condition¹⁸

$$(\partial p / \partial V)_s = -(p - p_0)/(V_0 - V). \quad (7)$$

In (6) the subscript 0 refers to the undetonated explosive, E_0 being given by the expression

$$E_0 = (\Delta H_f)_e + \sum_j N_j [H^0(T_0) - H_0^0]_j - p_0 V_0, \quad (8)$$

where $(\Delta H_f)_e$ is the molar enthalpy of formation of the explosive at T_0 , and N_j is the number of moles of element j in one mole of explosive.

3. CALCULATIONS

The detonation products were assumed to be made up of the following chemical components:

- (1) H_2 , (2) CO_2 , (3) CO , (4) H_2O , (5) N_2 ,
(6) NO , (7) C (graphite). (9)

Oxygen was not included, since none of the explosives considered was more oxygen rich than RDX, which balances to N_2 , H_2O , CO . In some preliminary calculations on IBM-CPC equipment some of the components considered by Brinkley, *et al.*,^{10,11} *viz.*, NH_3 , CH_4 , and OH , were also included; these were found to be present in small though not negligible amounts. For

¹⁶ In evaluating the thermodynamic functions for the solid we neglected $(pV_s)^0$ and approximated $V_s^0(T)$ by $V_s^0(25^\circ C)$. The resulting error was less than that of the analytic fits used for $(H^0 - H_0^0)$ and S^0 .

¹⁷ See, for example, R. Courant and K. O. Friedrichs, *Supersonic Flow and Shock Waves* (Interscience Publishers, Inc., New York, 1948), p. 204.

¹⁸ In the usual statement of the C-J condition, $(\partial p / \partial V)_s$ is to be evaluated for equilibrium composition. However, Kirkwood and Wood [J. Chem. Phys. 22, 1915 (1954)] have recently shown that this derivative should be evaluated with frozen composition. Our calculations have used the older statement of the C-J condition, but there is very little difference between the two, at least for our equation of state. Check calculations showed that the use of the correct C-J condition would decrease p_{CJ} by less than 1% at the lowest loading density of interest ($\rho_0 = 1.2$) and make almost no change at high loading density.
