

ments. Thus the deformation lamellae may be related genetically to the movements which produced the large-scale folding of the Baraboo syncline. Although the movements may have been complex when considered in detail, as Riley has maintained, it is not impossible to incorporate the deformation lamellae and the folding in a single movement-picture.

ACKNOWLEDGMENTS

This paper reports the results of work carried out at Pomona College, Claremont, California, as part of a research project financed by the National Science Foundation; this support is gratefully acknowledged. We are indebted to Professor D. B. McIntyre for helpful discussion during the course of the study and the preparation of the manuscript. We are also very grateful to Professor F. J. Turner, who read the manuscript and made several very valuable suggestions; and to Professor D. T. Griggs, Professor G. Tunell and Dr. L. E. Weiss for helpful criticism and advice regarding the manuscript.
