tion of void space in the liquid is in excellent agreement with the Eyring theory of holes in liquids.<sup>22</sup>

Figure 11 presents log-log plots for methanol, benzene, and carbon disulfide. Additional shock compression data, using the aquarium method,<sup>14</sup> were obtained in this study, and the results are given in Table IV along with those obtained from the log-log plots. Again, straight lines characterized the log-log plots at high pressures.

## Murnaghan Equation Comparison

Finally, it is of interest to compare Eq. (13) to the Murnaghan equation of state<sup>23</sup> derived from finite

strain theory, namely,

$$v_0/v = \left[1 + kp/(\lambda_0 + \frac{2}{3}\mu_0)\right]^{1/k}, \tag{23}$$

where  $\lambda_0$  and  $\mu_0$  are the Lamé elastic constants, and k is a constant which was assumed to be  $\frac{1}{3}$  from the "(drastic) assumption that  $\lambda$  and  $\mu$  are independent of  $p_0$ ." Equation (23) becomes identical with Eq. (13) if one assumes that a=1/k and  $p_i=(\lambda_0+\frac{2}{3}\mu_0)/k$ . Murnaghan also points out that as  $v \to \infty$ ,  $p \to -(\lambda_0 + \frac{2}{3}\mu_0)/k$ , and that the medium in theory would support a hydrostatic tension of  $(\lambda_0 + \frac{2}{3}\mu_0)/k$  before rupture. This is the force required to overcome the cohesive forces of the medium, and one can conclude that the assumption of  $p_i = \epsilon_c / v_0 = (\lambda_0 + \frac{2}{3}\mu_0)/k$  is not unreasonable. On the other hand, obtaining good workable values for k has presented some difficulty and empirical values are generally used. From the values of a given in Table I, one observes that the rough assumption of  $k = \frac{1}{3}$  is quite good in many cases, but is also seriously in error for many cases compared to the present work. The fact that the present theory yields an equation of state of the same form as that of Murnaghan, however, lends support to the validity of the present theory.
