## PRESSURE DEPENDENCE OF THE CARRIER CONCENTRATIONS...

FIG. 5. Number of electrons in sample 7B as a function of pressure. The points are the values of *n* deduced from the experimental data. The lines are calculated from the Kane's  $\vec{k} \cdot \vec{p}$  model with  $P_K = 8.4 \times 10^{-8}$  eV/cm,  $\alpha = dE_g/dP = 7.0 \times 10^{-6}$  eV/bar.

kbar), *R* is constant initially and then shows strong quantum effects but remains negative. The resistivity rises very rapidly with transverse magnetic field from 0.03  $\Omega$  cm to more than 80  $\Omega$  cm at 20 kG. At high fields the Hall angle was less

FIG. 6. Electron mobility as a function of pressure for the three samples. The variation of the reciprocal effective mass due to the change in  $E_g$  is shown by the dashed lines for comparison. The mobility is seen to increase faster than  $1/m^*$  at low pressure, and for sample 7B at 4.2 °K to turn downward above 2 kbar.
