

$$\begin{aligned}\vec{r} &\equiv \vec{r}_\kappa - \vec{R}_\kappa, \quad \vec{z} \equiv \vec{r}_\lambda - \vec{R}_\lambda, \\ \vec{Y} &\equiv \vec{r}_s - \vec{R}_s = \vec{r}_\rho - \vec{R}_\rho.\end{aligned}\quad (20)$$

Six random numbers were chosen for the components of the \vec{r} and \vec{z} vectors. Importance sampling was used for the two random numbers chosen for $|\vec{r}|$ and $|\vec{z}|$. It was found that biasing the other four variables had a much smaller effect on statis-

tics and was therefore not employed. For this six-dimensional point in phase space $G(\vec{r}_\lambda, \vec{r}_\kappa)$ was evaluated using one of the above techniques. This process was repeated for a total of typically 10 000 to 100 000 points. It is estimated that the computer time used was approximately an order of magnitude less than for a full Monte Carlo simulation for comparable statistical errors.
