Table I: A_p/A_1 for Aqueous Solutions of $\text{La}_2(\text{SO}_4)_3$ at 25°

Electrical conductance as a function of pressure up to 2000 atm has been measured on aqueous solutions of lanthanum sulphate at 25° at seven concentrations from 0.0002 to 0.0082 equiv/l. The effect of pressure on the dissociation constant of the $\text{La}(\text{SO}_4)_3^+$ complex ion pair was calculated using three different methods. At atmospheric pressure ΔV ranged from -21.2 to -26.2 ml/mole and at 2000 atm ΔV ranged from -6.8 to -11.8 ml/mole depending on the method used and concentration. Based on the atmosphere pressure value of $T_2^o = -23.8$ for $\text{La}(\text{SO}_4)_3^+$ the partial molar volume of the $\text{La}(\text{SO}_4)_3^+$ ion at the lowest concentration is -0.9 to 0.2 ml/mole.

where x is the concentration in equivalents of the $(\text{LaSO}_4)^+$ complex ion and π^f is the activity coefficient product.

Calculations were made using the mixture rule in which the solution is regarded as a mixture⁹ of a 1-2 salt, $(\text{LaSO}_4)_2\text{SO}_4$, at equivalent concentration x and the 3-2 salt, $\text{La}_2(\text{SO}_4)_3$, at equivalent concentration $c - 3x$. The observed equivalent conductance of the solution is written then as

$$\Lambda_{\text{obs}} = (x/c)\Lambda_{12} + (c - 3x)/c\Lambda_{23} \quad (3)$$

where the Λ_{12} and Λ_{23} are calculated from theory and x is solved for by successive approximations. The activity coefficient product is⁶

$$\pi^f = [(f_{32\pm})^{5/2}/(f_{12\pm})^{3/2}] \quad (4)$$

where

$$-\log f_{ij\pm} = (A|z_i z_j| \sqrt{I})/(1 + B\delta \sqrt{I}) \quad (5)$$

and the ionic strength $I = 2.5c - 6x$.

Calculations of x and K were made using three different methods as follows.

Method a: The Davies-Otter-Prue equation with appropriate modifications for pressure-dependent terms^{2b}

$$\Lambda = \Lambda^\circ - [(R\Lambda^\circ/(1 + B\delta \sqrt{I/2})) + E] \times (\sqrt{I/(1 + B\delta \sqrt{I})}) \quad (6)$$

was used to calculate the equivalent conductance. Bjerrum distances (at atmospheric pressure) of 21.4 Å for the 3-2 and 7.14 Å for the 1-2 salt were used for δ and the same pressure dependence was applied as in the MgSO_4 work.

Method b: Equation 6 was used but distances of $\delta = 5$ Å for the 3-2 and $\delta = 3.6$ Å for the 1-2 salt were used; these are the same values that Spedding and Jaffe used.

Method c: The Onsager equation⁹

$$\Lambda = \Lambda^\circ - [R\Lambda^\circ + E]\sqrt{I} \quad (7)$$

was used to calculate the equivalent conductance and the δ distances of 5 and 3.6 Å were used in the activity coefficient calculation.

The pressure-dependent forms of eq. 6 and 7 were used to calculate x and K as a function of pressure in a manner similar to that described earlier,^{2b} and the results for x in molar units are shown in Table IV. The molal dissociation constant, K_m , shown in Table V was obtained by dividing the values of K in molar units by the ratio of the density of water at pressure P to that at atmospheric pressure.

From the equation^{2a}

$$(\partial \ln K_m / \partial p)_{T,m} = -(\Delta V^\circ / RT) \quad (8)$$

values of ΔV° are calculated corresponding to the three different methods and are shown in Table VI.

The pressure dependence of infinite dilution equivalent conductivity, Λ_p° , for the $\text{La}_2(\text{SO}_4)_3$ was determined from the equation

$$\Lambda_p^\circ [\text{La}_2(\text{SO}_4)_3] = \Lambda_p^\circ [\text{LaCl}_3] + \Lambda_p^\circ [\text{K}_2\text{SO}_4] - \Lambda_p^\circ [\text{KCl}] \quad (9)$$

The Λ_p° values for the La^{3+} and SO_4^{2-} ions were calculated using the KCl transference number data of Wall and Gill.¹⁰ It was assumed that their transference number data to 1000 atm could be extrapolated linearly to 2000 atm. The Jenkins and Monk⁷ value for
