

FIG. 8. Comparison of present and previous high-temperature  $K$  versus  $T$  results for Ge.

of the two experiments. The reason for this probably real discrepancy is not completely understood.

#### INTERPRETATION OF LOW-TEMPERATURE MEASUREMENTS

In the temperature range below 300°K, the  $K$  results on Si and Ge can be interpreted using Callaway's formalism.<sup>37-39</sup> The  $K$  due to heat transport by phonons is

TABLE II. Literature references to the thermal conductivity of Si and Ge for  $T \geq 300^{\circ}\text{K}$ .

given by

$$K = \frac{k}{2\pi^2 v} \left( \frac{kT}{\hbar} \right)^3 \int_0^{\theta/T} \tau_C(x, T) \frac{x^4 e^x}{(e^x - 1)^2} dx, \quad (1)$$

where  $k$  = Boltzmann's constant,  $v$  = average sound velocity,  $T$  = absolute temperature,  $\hbar$  = Planck's constant,  $\theta$  = Debye temperature,  $x = (\hbar\omega/kT)$ ,  $\omega$  = phonon frequency, and  $\tau_C$  is a combined relaxation time. The complicating effects<sup>37</sup> of normal phonon scattering have been neglected. The combined relaxation time is thus taken as

$$\tau_C^{-1} = \tau_B^{-1} + \tau_I^{-1} + \tau_U^{-1}, \quad (2)$$

where  $\tau_B$ ,  $\tau_I$ ,  $\tau_U$  are the relaxation times for boundary, isotope, and umklapp scattering of the phonons.

The particular form of the relaxation times shall now be examined. Klemens<sup>40,41</sup> has derived a relaxation time for scattering by point imperfections. His results are valid for isotope scattering.

$$\tau_I^{-1}(\omega) = 3V_0\Gamma\omega^4/\pi v^3, \quad (3)$$

where  $V_0$  = average volume per atom in the crystal, and  $\Gamma$  = point impurity scattering parameter.<sup>42</sup> For umklapp scattering the following semiempirical expression<sup>43</sup> will be used:

$$\tau_U^{-1} = B_U \omega^2 T. \quad (4)$$
