

Fig. 5. In the calcite-hydrogen system, plot of mole $\% \mathrm{CH}_{4}$ generated and residual ( $\mathrm{O}_{2}$ remaining as calcite in experiments run for 2 hours; $2000 \mathrm{psi}\left(\mathrm{H}_{2}\right)$; at $535,605,735$, i\%, and $870^{\circ} \mathrm{C}$.

Analysis of the reaction gases shows that the reaction compounds are restricted in number even though a large population of compounds are possible in the C-H-O system. The gases present are the following: $\mathrm{CH}_{4}$; $\mathrm{C}_{2} \mathrm{H}_{6} ; \mathrm{H}_{2} \mathrm{O} ; \mathrm{CO}$; and $\mathrm{CO}_{2}$. The latter two appeared in only one experiment (no. 75). This experiment was unique in that the original hydrogen pressure was only 200 psi. ${ }^{1}$ The appearance of CO and $\mathrm{CO}_{2}$ at low pressures may be explained, at least in part, through thermodynamic calculations for a simplified C-H-O gaseous system (French, 1966). These calculations show that decreasing pressure favors the formation of $\mathrm{CO}_{2}$ and water relative to methane and are in agreement with our experimental lindings.
It appears that methane and, if within the stability field, homologues of methane, form directly rather than from reactions between hydrogen
${ }^{1}$ Fugacitics vary with pressure, consequently the proportion of each substance present in the equilibrium will also vary with pressure.
