

Petrographic examination of the alteration zone material obtained at 67.5 kilobars and 2000° C. showed essentially two phases (Fig. 4): a very fine-grained, markedly birefringent, rod-like material (kyanite), and a somewhat more coarsely grained, faky phase of lower birefringence. Petrographic examination of the alteration zone material obtained at 67.5 kilobars and 2000° C. is probably the same phase as that noted by Carte (1955).

This is probably the change that occurred from the  $\alpha$ -hydrate standard pressure and 1000° C. is essentially a dehydrated phase, the  $\alpha$ -kyanite up to a pressure between 27 and 40.5 kilobars, above which coesite is the principal phase. The "modified pyrophyllite" obtained at standard pressure and 1000° C. is probably a dehydrated phase, the  $\alpha$ -kyanite up to a pressure between 27 and 40.5 kilobars, above which coesite is the principal phase. The "modified pyrophyllite" obtained at standard pressure and 1000° C. is probably a dehydrated phase, the  $\alpha$ -kyanite up to a pressure between 27 and 40.5 kilobars, above which coesite is the principal phase. TABLE I. PYROPHYLLITE REACTION PRODUCTS

(coesite). The kyanite appeared more uniform in crystallite size, averaging approximately  $1 \times 5\mu$ . Coesite, on the other hand, showed fragments as small as  $1\mu$  and large flakes up to  $40 \times 85\mu$ .

Since the original synthesis of coesite (Coes, 1953), interest in this material has grown steadily, the pace having been quickened by its recent discovery at Meteor Crater, Arizona (Chao, Shoemaker and Madsen, 1960). This positive identification of a natural occurrence firmly estab-

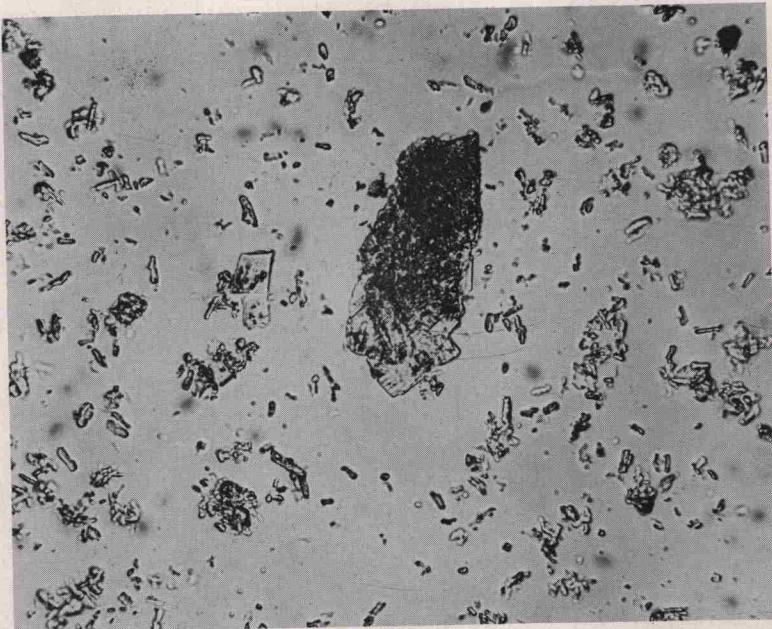

FIG. 4. Photomicrograph showing kyanite (fine-grained, rod-like) and coesite (large flakes) from alteration zone material obtained at 67.5 kilobars and 2000° C.; transmitted light, 1.54 immersion oil (390X).

lishes the mineralogical name coesite, as opposed, for example, to the term "silica-C" (Sosman, 1954). The general crystallography of coesite (Ramsdell, 1955) and its crystal structure (Zoltai and Buerger, 1959) have been described, along with further accounts of its synthesis and characteristics (Khitarev, Slutskiy and Arsen'yeva, 1957). In addition, several studies have been made of quartz-coesite relationships (MacDonald 1956; Dachille and Roy, 1959; Boyd and England, 1960).

As of 1954, the synthesis of kyanite had not yet been achieved, the difficulty having been ascribed to the required octahedral coordination for  $\text{Al}^{3+}$  (Roy and Osborn, 1954). More recent investigations, however,
